

Package: DynForest (via r-universe)

August 31, 2024

Title Random Forest with Multivariate Longitudinal Predictors

Version 1.1.3

Description Based on random forest principle, 'DynForest' is able to include multiple longitudinal predictors to provide individual predictions. Longitudinal predictors are modeled through the random forest. The methodology is fully described for a survival outcome in: Devaux, Helmer, Genuer & Proust-Lima (2023) <[doi:10.1177/09622802231206477](https://doi.org/10.1177/09622802231206477)>.

compute_gVIMP	<i>Compute the grouped importance of variables (gVIMP) statistic</i>
---------------	--

Description

Compute the grouped importance of variables (gVIMP) statistic

Usage

```
compute_gVIMP(
  DynForest_obj,
  IBS.min = 0,
  IBS.max = NULL,
  group = NULL,
  ncores = NULL,
  seed = 1234
)
```

Arguments

DynForest_obj	DynForest object containing the dynamic random forest used on train data
IBS.min	(Only with survival outcome) Minimal time to compute the Integrated Brier Score. Default value is set to 0.
IBS.max	(Only with survival outcome) Maximal time to compute the Integrated Brier Score. Default value is set to the maximal time-to-event found.
group	A list of groups with the name of the predictors assigned in each group
ncores	Number of cores used to grow trees in parallel. Default value is the number of cores of the computer-1.
seed	Seed to replicate results

Value

compute_gVIMP() function returns a list with the following elements:

Inputs	A list of 3 elements: Longitudinal, Numeric and Factor. Each element contains the names of the predictors
group	A list of each group defined in group argument
gVIMP	A numeric vector containing the gVIMP for each group defined in group argument
tree_oob_err	A numeric vector containing the OOB error for each tree needed to compute the VIMP statistic
IBS.range	A vector containing the IBS min and max

Examples

```

data(pbc2)

# Get Gaussian distribution for longitudinal predictors
pbc2$serBilir <- log(pbc2$serBilir)
pbc2$SGOT <- log(pbc2$SGOT)
pbc2$albumin <- log(pbc2$albumin)
pbc2$alkaline <- log(pbc2$alkaline)

# Sample 100 subjects
set.seed(1234)
id <- unique(pbc2$id)
id_sample <- sample(id, 100)
id_row <- which(pbc2$id%in%id_sample)

pbc2_train <- pbc2[id_row,]

timeData_train <- pbc2_train[,c("id", "time",
                               "serBilir", "SGOT",
                               "albumin", "alkaline")]

# Create object with longitudinal association for each predictor
timeVarModel <- list(serBilir = list(fixed = serBilir ~ time,
                                   random = ~ time),
                    SGOT = list(fixed = SGOT ~ time + I(time^2),
                                random = ~ time + I(time^2)),
                    albumin = list(fixed = albumin ~ time,
                                   random = ~ time),
                    alkaline = list(fixed = alkaline ~ time,
                                    random = ~ time))

# Build fixed data
fixedData_train <- unique(pbc2_train[,c("id", "age", "drug", "sex")])

# Build outcome data

                    ntree = 50, nodesize = 5, minsplit = 5,
                    cause = 2, ncores = 2, seed = 1234)

# Compute gVIMP statistic
res_dyn_gVIMP <- compute_gVIMP(DynForest_obj = res_dyn,
                              group = list(group1 = c("serBilir","SGOT"),
                                             group2 = c("albumin","alkaline")),
                              ncores = 2, seed = 1234)

```

compute_OOBerror	<i>Compute the Out-Of-Bag error (OOB error)</i>
------------------	---

Description

Compute the Out-Of-Bag error (OOB error)

Usage

```
compute_OOBerror(DynForest_obj, IBS.min = 0, IBS.max = NULL, ncores = NULL)
```

Arguments

DynForest_obj	DynForest object containing the dynamic random forest used on train data
IBS.min	(Only with survival outcome) Minimal time to compute the Integrated Brier Score. Default value is set to 0.
IBS.max	(Only with survival outcome) Maximal time to compute the Integrated Brier Score. Default value is set to the maximal time-to-event found.
ncores	Number of cores used to grow trees in parallel. Default value is the number of cores of the computer-1.

Value

compute_OOBerror() function return a list with the following elements:

data	A list containing the data used to grow the trees
rf	A table with each tree in column. Provide multiple characteristics about the tree building
type	Outcome type

times	A numeric vector containing the time-to-event for all subjects
cause	Indicating the cause of interest
causes	A numeric vector containing the causes indicator
Inputs	A list of 3 elements: Longitudinal, Numeric and Factor. Each element contains the names of the p
Longitudinal.model	A list of longitudinal markers containing the formula used for modeling in the random forest
param	A list containing the hyperparameters
oob.err	A numeric vector containing the OOB error for each subject
oob.pred	Outcome prediction for all subjects
IBS.range	A vector containing the IBS min and max

Examples

```

data(pbc2)

# Get Gaussian distribution for longitudinal predictors

```

compute_VIMP

Compute the importance of variables (VIMP) statistic

Description

Compute the importance of variables (VIMP) statistic

Usage

```

compute_VIMP(
  DynForest_obj,
  IBS.min = 0,
  IBS.max = NULL,
  ncores = NULL,
  seed = 1234
)

```

Arguments

DynForest_obj	DynForest object containing the dynamic random forest used on train data
IBS.min	(Only with survival outcome) Minimal time to compute the Integrated Brier Score. Default value is set to 0.
IBS.max	(Only with survival outcome) Maximal time to compute the Integrated Brier Score. Default value is set to the maximal time-to-event found.
ncores	Number of cores used to grow trees in parallel. Default value is the number of cores of the computer-1.
seed	Seed to replicate results

Value

compute_VIMP() function returns a list with the following elements:

Inputs	A list of 3 elements: Longitudinal, Numeric and Factor. Each element contains the names of the predictors
Importance	A list of 3 elements: Longitudinal, Numeric and Factor. Each element contains a numeric vector of VIMP
tree_oob_err	A numeric vector containing the OOB error for each tree needed to compute the VIMP statistic
IBS.range	A vector containing the IBS min and max

Examples

```

data(pbc2)

# Get Gaussian distribution for longitudinal predictors

```

`DynForest`*Random forest with multivariate longitudinal endogenous covariates*

Description

Build a random forest using multivariate longitudinal endogenous covariates

Usage

```

DynForest(
  timeData = NULL,
  fixedData = NULL,
  idVar = NULL,
  timeVar = NULL,
  timeVarModel = NULL,
  Y = NULL,
  ntree = 200,
  mtry = NULL,
  nodesize = 1,
  minsplit = 2,
  cause = 1,
  nsplit_option = "quantile",
  ncores = NULL,
  seed = 1234,
  verbose = TRUE
)

```

Arguments

<code>timeData</code>	A data.frame containing the id and time measurements variables and the time-dependent predictors.
<code>fixedData</code>	A data.frame containing the id variable and the time-fixed predictors. Categorical variables should be characterized as factor.
<code>idVar</code>	A character indicating the name of variable to identify the subjects
<code>timeVar</code>	A character indicating the name of time variable
<code>timeVarModel</code>	A list for each time-dependent predictors containing a list of formula for fixed and random part from the mixed model
<code>Y</code>	A list of output which should contain: type defines the nature of the outcome, can be "surv", "numeric" or "factor"; .
<code>ntree</code>	Number of trees to grow. Default value set to 200.
<code>mtry</code>	Number of candidate variables randomly drawn at each node of the trees. This parameter should be tuned by minimizing the OOB error. Default is defined as the square root of the number of predictors.
<code>nodesize</code>	Minimal number of subjects required in both child nodes to split. Cannot be smaller than 1.
<code>minsplit</code>	(Only with survival outcome) Minimal number of events required to split the node. Cannot be smaller than 2.
<code>cause</code>	(Only with competing events) Number indicates the event of interest.
<code>nsplit_option</code>	A character indicates how the values are chosen to build the two groups for the splitting rule (only for continuous predictors). Values are chosen using deciles (<code>nsplit_option="quantile"</code>) or randomly (<code>nsplit_option="sample"</code>). Default value is "quantile".

ncores	Number of cores used to grow trees in parallel. Default value is the number of cores of the computer-1.
seed	Seed to replicate results
verbose	A logical controlling the function progress. Default is TRUE

Details

The function currently supports survival (competing or single event), continuous or categorical outcome.

FUTUR IMPLEMENTATIONS:

- Continuous longitudinal outcome
- Functional data analysis

Value

DynForest function returns a list with the following elements:

data	A list containing the data used to grow the trees
rf	A table with each tree in column. Provide multiple characteristics about the tree building
type	Outcome type
times	A numeric vector containing the time-to-event for all subjects
cause	Indicating the cause of interest
causes	A numeric vector containing the causes indicator
Inputs	A list of 3 elements: Longitudinal, Numeric and Factor. Each element contains the names of the p
Longitudinal.model	A list of longitudinal markers containing the formula used for modeling in the random forest
param	A list containing the hyperparameters
comput.time	Computation time

getTree	<i>Extract some information about the split for a tree by user</i>
---------	--

Description

Extract some information about the split for a tree by user

Usage

```
getTree(DynForest_obj, tree)
```

Arguments

DynForest_obj	DynForest object containing the dynamic random forest used on train data
tree	Integer indicating the tree identifier

Value

A table sorted by the node/leaf identifier with each row representing a node/leaf. Each column provides information about the splits:

type	The nature of the predictor (Longitudinal for longitudinal predictor, Numeric for continuous predictor or Factor)
var_split	The predictor used for the split defined by its order in timeData and fixedData
feature	The feature used for the split defined by its position in random statistic
threshold	The threshold used for the split (only with Longitudinal and Numeric). No information is returned for Factor
N	The number of subjects in the node/leaf
Nevent	The number of events of interest in the node/leaf (only with survival outcome)
depth	the depth level of the node/leaf

```

pbc2

pbc2 dataset

Description

pbc2 data from Mayo clinic

Format

Longitudinal dataset with 1945 rows and 19 columns for 312 patients

id Patient identifier

time Time measurement

ascites Presence of ascites (Yes/No)

hepatomegaly Presence of hepatomegaly (Yes/No)

spiders Blood vessel malformations in the skin (Yes/No)

edema Edema levels (No edema/edema no diuretics/edema despite diuretics)

serBilir Level of serum bilirubin

serChol Level of serum cholesterol

plot.DynForest	<i>Plot function in DynForest</i>
----------------	-----------------------------------

Description

This function displays a plot of CIF for a given node and tree (for class `DynForest`), the most predictive variables with the minimal depth (for class `DynForestVarDepth`), the variable importance (for class `DynForestVIMP`) or the grouped variable importance (for class `DynForestgVIMP`).

Usage

```
## S3 method for class 'DynForest'
plot(x, tree = NULL, nodes = NULL, id = NULL, max_tree = NULL, ...)

## S3 method for class 'DynForestVarDepth'
plot(x, plot_level = c("predictor", "feature"), ...)

## S3 method for class 'DynForestVIMP'
plot(x, PCT = FALSE, ordering = TRUE, ...)

## S3 method for class 'DynForestgVIMP'
plot(x, PCT = FALSE, ...)

## S3 method for class 'DynForestPred'
plot(x, id = NULL, ...)
```

Arguments

x	Object inheriting from classes <code>DynForest</code> , <code>DynForestVarDepth</code> , <code>DynForestVIMP</code> or <code>DynForestgVIMP</code> , to respectively plot the CIF, the minimal depth, the variable importance or grouped variable importance.
tree	For <code>DynForest</code> class, integer indicating the tree identifier
nodes	For <code>DynForest</code> class, identifiers for the selected nodes
id	For <code>DynForest</code> and <code>DynForestPred</code> classes, identifier for a given subject
max_tree	For <code>DynForest</code> class, integer indicating the number of tree to display while using id argument
...	Optional parameters to be passed to the low level function

plot_level	For DynForestVarDepth class, compute the statistic at predictor (plot_level="predictor") or feature (plot_level="feature") level
PCT	For DynForestVIMP or DynForestgVIMP class, display VIMP statistic in percentage. Default value is FALSE.
ordering	For DynForestVIMP class, order predictors according to VIMP value. Default value is TRUE.

Value

plot() function displays:

With DynForestVarDepth	the minimal depth for each predictor/feature
With DynForestVIMP	the VIMP for each predictor
With DynForestgVIMP	the grouped-VIMP for each given group

predict.DynForest *Prediction using dynamic random forests*

Description

Prediction using dynamic random forests

Usage

```

## S3 method for class 'DynForest'
predict(
  object,
  timeData = NULL,
  fixedData = NULL,
  idVar,
  timeVar,
  t0 = NULL,
  ...
)

```

Arguments

object	DynForest object containing the dynamic random forest used on train data
timeData	A data.frame containing the id and time measurements variables and the time-dependent predictors.
fixedData	A data.frame containing the id variable and the time-fixed predictors. Non-continuous variables should be characterized as factor.
idVar	A character indicating the name of variable to identify the subjects
timeVar	A character indicating the name of time variable
t0	Landmark time
...	Optional parameters to be passed to the low level function

Value

Return the outcome of interest for the new subjects: matrix of probability of event of interest in survival mode, average value in regression mode and most likely value in classification mode

Examples

```

data(pbc2)

# Get Gaussian distribution for longitudinal predictors

```

print.DynForest *Print function*

Description

This function displays a brief summary regarding the trees (for class `DynForest`), a data frame with variable importance (for class `DynForestVIMP`) or the grouped variable importance (for class `DynForestgVIMP`).

Usage

```

## S3 method for class 'DynForest'
print(x, ...)

## S3 method for class 'DynForestVIMP'
print(x, ...)

## S3 method for class 'DynForestgVIMP'
print(x, ...)

## S3 method for class 'DynForestVarDepth'
print(x, ...)

## S3 method for class 'DynForest00B'
print(x, ...)

## S3 method for class 'DynForestPred'
print(x, ...)

```

Arguments

`x` Object inheriting from classes `DynForest`, `DynForestVIMP` or `DynForestgVIMP`.
`...` Optional parameters to be passed to the low level function

var_depth	<i>Extract characteristics from the trees building process</i>
-----------	--

Description

Extract characteristics from the trees building process

Usage

```
var_depth(DynForest_obj)
```

Arguments

DynForest_obj DynForest object

Value

var_depth function return a list with the following elements:

min_depth A table providing for each feature in row: the average depth and the rank

var_node_depth A table providing for each tree in column the minimal depth for each feature in row. NA indicates that the

var_count A table providing for each tree in column the number of times where the feature is used (in row). 0 value
